CAS INDEXING IS AVAILABLE FOR THIS PATENT.
AB     Multilayer optical films having one or more reflection bands are
       provided. The films include alternating polymeric layers configured to
       selectively reflect and transmit visible light at a design angle of
       incidence, where the selective reflection includes first and second
       visible reflection bands. At least one of the first and second visible
       reflection bands is a first-order reflection.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB Methods and apparatuses are provided for the manufacture of coextruded polymeric multilayer optical films. The multilayer optical films have an ordered arrangement of layers of two or more materials having particular layer thicknesses and a prescribed layer thickness gradient throughout the multilayer optical stack. The methods and apparatuses described allow improved control over individual layer thicknesses, layer thickness gradients, indices of refraction, interlayer adhesion, and surface characteristics of the optical films. The methods and apparatuses described are useful for making interference polarizers, mirrors, and colored films that are optically effective over diverse portions of the ultraviolet, visible, and infrared spectra.

AB Disclosed herein are an olefinic thermoplastic elastomer sheet which has the same rubber elasticity, flexibility and molding or forming and processing ability as those of the conventional olefinic thermoplastic elastomer sheets and is good in mechanical properties and excellent in mar resistance in particular, a production process thereof, and a laminate having a surface layer composed of this sheet. The olefinic thermoplastic elastomer sheet according to the present invention is composed of an elastomer material comprising an olefin random copolymer obtained by copolymerizing ethylene, an α-olefin having 3 to 10 carbon atoms and an unsaturated monomer having a functional group, and optionally a non-conjugated diene, and a metal ion for crosslinking the olefin random copolymer.

AB Methods and apparatuses are provided for the manufacture of coextruded polymeric multilayer optical films. The multilayer optical films have an ordered arrangement of layers of two or more materials having particular layer thicknesses and a prescribed layer thickness gradient throughout the multilayer optical stack. The methods and apparatuses described allow improved control over individual layer thicknesses, layer thickness gradients, indices of refraction, interlayer adhesion, and surface characteristics of the optical films. The methods and apparatuses described are useful for making interference polarizers, mirrors, and colored films that are optically effective over diverse portions of the ultraviolet, visible, and infrared spectra.

AB The present invention relates to compositions such as fibers, elastic yarns, wovens, nonwovens, knitted fabrics, fine nets, and articles produced at least in part from a styrenic block copolymer comprising at least two blocks produced from vinyl aromatic monomers and at least one block produced from alkyl-substituted, conjugated alkene monomers, where the block produced from the conjugated alkene may have sufficient substitution so as to prevent or significantly minimize thermal cross-linking of the residual unsaturation in the formed block during fiber formation. Additionally, the composition may be described as processable, without requiring any additives if, for example, the order-disorder-transition (ODT) temperature is less than about 280° C.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB The electrode of the present invention is provided with an active material-containing layer comprising as the structural material composite particles composed of an electrode active material, a conductive additive and a binder, and a current collector in electrical

contact with the layer. The composite particles are formed by integrating the conductive additive and binder with the electrode active material particles. The active material-containing layer is formed by subjecting powder comprising at least the composite particles to pressurization treatment to form a sheet, and placing the sheet at the location of the current collector at which the active material-containing layer is to be formed. The electrode active material and conductive additive in the active material-containing layer are non-isolated and electrically linked. This construction allows an electrode with excellent electrical characteristics to be realized, which exhibits adequately reduced internal resistance and easily permits increased energy density to be achieved for electrochemical devices.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB An optical film is provided which comprises a disperse phase of polymeric particles disposed within a continuous birefringent matrix in combination with light directing materials to enable control of light emitted from a lighting fixture or display. The film is oriented, typically by stretching, in one or more directions. The size and shape of the disperse phase particles, the volume fraction of the disperse phase, the film thickness, and the amount of orientation are chosen to attain a desired degree of diffuse reflection and total transmission of electromagnetic radiation of a desired wavelength in the resulting film, and the light directing materials are chosen to control the direction of polarized light reflected from or transmitted by the optical film.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB The present invention relates to a styrene copolymer and the method of preparing the same through the steps described in the following:

A step of making a living polymer with an active anion by polymerizing an anionically polymerizable monomer in a non polar solvent in the presence of alkyllithum catalyst;

A step of preparing a macro monomer by reacting the abovementioned living polymer with a terminal modifier represented by the structure of formula 1 and

a step of copolymerizing the above macro monomer with styrene monomer with transition catalyst and co-catalyst.

The styrene copolymer, thus prepared, comprises repeated units of styrene monomers and repeated units of the macro monomers. The repeated monomers of styrene has syndiotactic structure.

The preparation method of the present invention provides high yield of syndiotactic styrene copolymer at room temperature. The present invention is characterized in that it utilizes styrene derivative, substituted with reactive chlorosilyl group as the terminal modifier, making a reactive and selective macromonomer at room temperature, and consequently preparing styrene copolymer effectively.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.
AB There are disclosed a block copolymer of at least one elastomeric block and at least one syndiotactic

polystyrene block which comprises 100 parts by weight of a polymer component comprising 1 to 80% by weight of syndiotactic polystyrene (sPS) block(s) and 99 to 20% by weight of rubbery elastomeric block(s) and at least 30 parts by weight of an extender. These extended block copolymer compositions display the characteristics of thermoplastic elastomers and are useful for high temperature applications possessing unique softness.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB Methods and apparatuses are provided for the manufacture of coextruded polymeric multilayer optical films. The multilayer optical films have an ordered arrangement of layers of two or more materials having particular layer thicknesses and a prescribed layer thickness gradient throughout the multilayer optical stack. The methods and apparatuses described allow improved control over individual layer thicknesses, layer thickness gradients, indices of refraction, interlayer adhesion, and surface characteristics of the optical films. The methods and apparatuses described are useful for making interference polarizers, mirrors, and colored films that are optically effective over diverse portions of the ultraviolet, visible, and infrared spectra.

AB An automotive molding, which is excellent in scratching resistance, has high gloss, and is excellent in weathering resistance. The automotive molding of the invention has a part composed of an elastomer material containing an olefinic random copolymer obtained by copolymerizing ethylene, an α-olefin having 3 to 10 carbon atoms and an unsaturated monomer having a functional group, and optionally a non-conjugated diene, and a metal ion for crosslinking the olefinic random copolymer.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB The present invention relates to a styrene copolymer and the method of preparing the same through the steps described in the following:

a step of making a living polymer with an active anion by polymerizing an anionically polymerizable monomer in a non polar solvent in the presence of alkyllithum catalyst;

a step of preparing a macro monomer by reacting the abovementioned living polymer with a terminal modifier represented by the structure of formula 1; and

a step of copolymerizing the above macro monomer with styrene monomer with transition catalyst and co-catalyst.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

DETD The syndiotactic vinyl aromatic copolymers of the present invention may be block copolymers, random copolymers, or alternating copolymers.

DETD The films and other optical devices made in accordance with the invention may also be provided with one or more adhesives to laminate the optical films and devices of the present invention to another film, surface, or substrate. Such adhesives include both optically clear and diffuse adhesives, as well as pressure sensitive and non-pressure sensitive adhesives. Pressure sensitive adhesives are normally tacky at room temperature and can be adhered to a surface by application of, at most, light finger pressure, while non-pressure sensitive adhesives include solvent, heat, or radiation activated adhesive systems. Examples of adhesives useful in the present invention include those based on general compositions of polyacrylate; polyvinyl ether, diene -containing rubbers such as natural rubber, polyisoprene, and polyisobutylene; polychloroprene; butyl rubber; butadiene -acrylonitrile polymers; thermoplastic elastomers; block copolymers such as styrene-isoprene and styrene-isoprene-styrene block copolymers, ethylene-propylene-diene polymers, and styrene-butadiene polymers; polyalphaolefins; amorphous polyolefins; silicone; ethylene-containing copolymers such as ethylene vinyl acetate, ethylacrylate, and ethylmethacrylate; polyurethanes; polyamides; polyesters; epoxies; polyvinylpyrrolidone and vinylpyrrolidone copolymers; and mixtures of the above. Additionally, the adhesives can contain additives such as tackifiers, plasticizers, fillers, antioxidants, stabilizers, pigments, diffusing particles, curatives, and solvents. In some applications, as where the optical films of the present invention are to be used as a component in adhesive tapes, it may be desirable to treat the films with low adhesion backsize (LAB) coatings or films such as those based on urethane, silicone or fluorocarbon chemistry. Films treated in this manner will exhibit proper release properties towards pressure sensitive adhesives (PSAs), thereby enabling them to be treated with adhesive and wound into rolls Adhesive tapes, sheets, or die-cuts made in this manner can be used for decorative purposes or in any application where a diffusely reflective or transmissive surface on the tape is desirable. When a laminating adhesive is used to adhere an optical film of the present invention to another surface, the adhesive composition and thickness are preferably selected so as not to interfere with the optical properties of the optical film. For example, when laminating additional layers to an optical polarizer or mirror wherein a high degree of transmission is desired, the laminating adhesive should be optically clear in the wavelength region that the polarizer or mirror is designed to be

transparent in.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

SUMM Several remedies have been introduced in order to improve impact resistance or impart elasticity to the syndiotactic polystyrene. U.S. Pat. No. 5,247,020, presents the method of blending syndiotactic polystyrene with elastomer during the polymerization process. The method suggests syndiotactic polymerization of styrene in the presence of elastomers such as styrene-butadiene block copolymer, or styrene-isoprene block copolymer.

SUMM Also, in order to solve the problem, presented are the methods of random or block copolymerization with other monomers. In U.S. Pat. No. 5,475,061 and U.S. Pat. No. 5,554,695, syndiotactic copolymerization with acryl monomer is presented. U.S. Pat. No. 5,260,394 describes random copolymer of syndiotactic polystyrene obtained by copolymerization with olefins such as ethylene and propylene or conjugated dienes such as butadiene and isoprene. The syndiotactic copolymers obtained by these methods have low glass transition temperatures, exhibiting enhanced processability and elasticity. U.S. Pat. No. 6,271,313 presents the syndiotactic polystyrene block copolymer prepared from styrene and butadiene monomer. But the activity of catalyst of the polymerization decreased in the presence of butadiene and both of low yield and low content of polybutadiene was resulted.

DETD Anionically polymerizable monomer of the present invention includes vinyl aromatic monomers such as styrene and p-methylstyrene, acryl monomers such as methyl acrylate, ethyl acrylate and methyl methacrylate, and conjugated dienes such as 1,3-butadiene and isoprene. Preferably one or more

monomers are selected from the group consisting of styrene, 1,3-butadiene and isoprene. When one anionically polymerizable monomer is used, the resulted polymer is homo polymer and two or more anionically polymerizable monomers are selected, block copolymer or random copolymer is made. In order to prepare block copolymer, the anionically polymerizable monomers are added in sequence, completing the polymerization of monomer at each step. The living polymers prepared as a block copolymer of the present invention include [polystyrene]-[polybutadiene anion], [polybutadiene]-[polystyrene anion], [polyisoprene]-[polystyrene anion], [polystyrene]-[polyisoprene anion].

DETD The molecular weight of the living polymer with anionic activity is 500-200,000 for homopolymer, 500-200,000 for random copolymer and 500-200,000 for block copolymer. The content of butadiene or isoprene in the living polymer is 10-90 weight %.

DETD All the chemicals used were distilled and kept under argon atmosphere. The atmosphere in a 2L reactor was replaced by argon gas. Into the reactor, added were 200 g of distilled cyclohexane and 10 g (96 mmol) of styrene and the temperature was maintained at 45° C. The initiator, 4 mL (5.2 mmol) of sec-butyllithium (BuLi) in cyclohexane solution (1.3M conc.) was added and the reaction was continued for 40 minutes. 40 g (0.74 mol) of butadiene was added and the reaction was run for 1 hour before the addition of 1.1 g (6 mmol) of p-chlorodimethylsilylstryene, the terminal modifier, which was dissolved in 5 mL cyclohexane. The reaction with the terminal modifier was run for 1 hour. The reaction was terminated by adding a few drops of degassed methanol. The product, macromonomer was filtered, washed several times with methanol, and the solvent was evaporated to obtain viscous oil. The synthesized polystyrene-block-polybutadiene macromonomer was stored in the dry-box freezer filled with argon gas. The structure of polystyrene-block-polybutadiene was determined by 1H-NMR.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

SUMM Block polymers, especially styrenic block copolymers (SBCs), generally are elastomeric materials that exhibit excellent solid-state elastic performance attributes. But the most common unsaturated block copolymers, styrene-butadiene-styrene triblock polymers (SBS), tend to exhibit mediocre thermal stability, especially in the molten state. In addition, SBS polymers readily form gels due to cross-linking at temperatures necessary to pass these materials through the fine holes of textile or nonwoven dies at commercial rates or draw-downs. Furthermore, drawing of SBS polymers as fibers at temperatures below their cross-linking temperature cannot be done at commercially viable levels due to ductile or melt fracture of the fiber.

SUMM One aspect of the present invention is a fiber produced from a composition comprising a copolymer that comprises at least two blocks produced from vinyl aromatic monomers and at least one block produced from conjugated alkene monomers. The copolymer includes a conjugated alkene block such that thermal cross-linking does not take place significantly at the processing temperature, usually between 200° and 280° C. It should be appreciated that by saying "no thermal cross-linking takes place"; it is meant that no appreciable cross-linking occurs that deleteriously affects processing. While not wishing to be bound by theory, it is believed that cross-linking is reduced in the soft block by limiting the amount of vinyl content (1,2 and/or 3,4 bonding in isoprene polymerization, for example) and/or by arrangements of the cis/trans unsaturation and/or by including steric groups to hinder the cross-linking reaction.

SUMM Surprisingly, it has been discovered that block copolymers having non-hydrogenated soft blocks (blocks originating from the conjugated alkene monomers) with sterically hindered chains, even though unsaturated, can be successfully melt drawn, including meltspun into fine denier fibers, where the comparative block polymer without sterically hindered chains (for example, butadiene blocks in SBS triblock copolymers) cannot be melt drawn nor melt spun into fibers. In one embodiment the fiber has a diameter of less than about 450 microns. In other embodiments, the fiber may have a diameter less than about 400 microns, less than about 200 microns, or less than 100 microns. This discovery is believed to be attributable to the surprising low shear melt viscosities of these block copolymers at processing temperatures (usually more than 30° C. above their ODTs). While not wishing to be bound by theory, the benefit of SIS-like polymers is also believed to be derived from their propensity to degrade by chain scission rather than cross-linking at high temperature. Chain scission is less of a detriment than cross-linking and at low levels may be an advantage to spinning. The higher temperature processing capability is most critical as it allows the polymer to be melted to an amorphous (disordered) state above the ODT onset. Materials which have residual order tend to form fibers that fail (break) ductilely when drawn at high velocities (>300 m/min). Comparatively, polymeric block materials, such as SBS, with similar molecular weights, exhibit significant cross-linking which fouls fiber spinning at the necessary processing temperatures or, if processed at temperatures below the onset of cross-linking, result in a melt with poor drawability and cannot be spun as fine fibers. In addition, it is well known that common hydrogenated species of this type (hydrogenated

SBS produces a block copolymer known as SEBS), even though they do not suffer cross-linking, cannot readily be drawn as fibers without extensive use of additives.

SUMM In view of the foregoing, it should be appreciated that in one broad respect, this invention is a fiber produced from a composition comprising 50 to 100 weight % of one or more block copolymer, wherein at least one of the non-hydrogenated block copolymers has at least two blocks produced from vinyl aromatic monomers and at least one block produced from alkyl-substituted (e.g., the alkyl being from one to ten carbons) conjugated alkene monomers, wherein the composition has an order/disorder transition (ODT) onset of less than 280° C., and neither the shear modulus, G', nor loss modulus, G", monotonically increase with temperature in the range from the ODT, or 150° C. in the absence of an ODT, to 280° C. In this respect, the fiber can have a composition that comprises up to 50% of a processing additive; the processing additive can be a fluorocarbon, a polyolefin, a mineral oil, a polysiloxane fluid, a tackifier, a wax, or combination thereof; the composition may include up to 5% of an additive to mitigate degradation of the fiber's properties, an additive to add color, luster, deluster, or filling, anti-block additive, a slip agent, or combination thereof; the block copolymer can be a triblock having two vinyl aromatic monomer unit blocks and one alkyl-substituted, conjugated alkene monomer unit block; the block copolymer can be a pentablock having three vinyl aromatic monomer unit blocks and two alkyl-substituted, conjugated alkene monomer unit blocks ; the conjugated alkene monomer can be isoprene; the conjugated alkene monomer can be of formula R.sub.2C.dbd.CR--CR.dbd.CR.sub.2, wherein the monomer has at least five carbons, and wherein each R, independently in each occurrence, is hydrogen or alkyl of from one to four carbons or any two R may form a ring; at least one of the vinyl aromatic monomers can be styrene; the fiber can have a diameter less than 400 microns; the fiber can be in the form of a conjugate fiber; the fiber can be in the form of a conjugate fiber which has a sheath/core or tipped multilobal (e.g., trilobal) cross section; the fiber can be in the form of a conjugate fiber, which has a sheath core or tipped multilobal (e.g., trilobal) cross section, wherein the sheath or the tip component is a polyolefin; the core comprises a styrene-isoprene-styrene triblock or higher copolymer; the core comprises a styrene-isoprene-styrene-isoprene-styrene pentablock or higher copolymer; or any combination thereof. The fiber can be used to form a woven or knitted fabric, yarn, filament, strand, or fine net. The fiber can be used to form a nonwoven, including a nonwoven wherein the nonwoven is spunlaid, or is meltblown, or any combinations thereof, wherein the fiber is a conjugate fiber, said conjugate fiber comprising the block copolymer and at least one polyolefin component, wherein said polyolefin component at least partially envelops the block copolymer, wherein the fibers are normally bonded at a temperature substantially below the bonding temperature of the polyolefin component, wherein the polyolefin is polyethylene and the normal bonding temperature is about 120-130° C., wherein the polyolefin is polypropylene and the normal bonding temperature is about 140° C., wherein the fiber is formed by extruding at a temperature above the ODT, wherein the fiber is extruded at a temperature at least 10° C. above the ODT, wherein the fiber is extruded at a temperature at least 50° C. above the ODT; or any combination thereof. The fiber can be drawn at a velocity of 300 m/min or greater. The fiber or nonwoven can be used to form a laminate wherein at least one layer comprises the fibers or fabrics

disclosed herein. The fibers can be used to form an article, including an article such as a disposable diaper, an elastic tab, a waist band, a leg cuff, a standing leg cuff, a side panel, an incontinent garment, a medical garment, a bandage or a textile apparel. The fiber or nonwoven can be produced by melt blowing, by a spunbond process, or by a combination thereof. The fiber can be made from other than the block copolymer. In the fiber, the block copolymer can be a styrene-isoprene block copolymer having a number average molecular weight styrene content per block of the block copolymer in the range from about 6,000 to about 45,000 grams/mole and/or having a number average molecular weight isoprene content per block of the block copolymer in the range from about 20,000 to about 150,000 grams/mole, with the total weight of styrene used-to make the block copolymer being 50% or less by weight.

SUMM In another broad respect, this invention is a fiber produced from a composition comprising 50% to 100% by weight of one or more block copolymers, wherein at least one block copolymer has at least two blocks produced from a vinyl aromatic monomer having up to 20 carbons and from a conjugated alkene monomer of formula: R.sub.2C.dbd.CR--CR.dbd.CR.sub.2 wherein each R, independently in each occurrence, is hydrogen, or alkyl of one to four carbons, or any two R join to form a ring, wherein the conjugated alkene monomer has at least five carbons and no more than 20 carbons. Preferably at least one R is alkyl, such as of from one to ten carbons. In this process, the composition may comprise up to 50% of a processing additive; the processing additive can be a fluorocarbon, a polyolefin, a mineral oil, a polysiloxane fluid, a tackifier, a wax, or combination thereof; the composition can include up to 5% of an additive to mitigate degradation of the fiber's properties; an additive to add color, luster, deluster, or filling; anti-block additive; a slip agent; or combination thereof; the block copolymer can be a triblock having two vinyl aromatic monomer unit blocks and one alkyl-substituted, conjugated alkene monomer unit block; the block copolymer can be a pentablock having two vinyl aromatic monomer unit blocks and two alkyl-substituted, conjugated alkene monomer unit blocks; the conjugated alkene monomer can be isoprene; at least one of the vinyl aromatic monomers can be styrene; the fiber can have a diameter less than 400 microns; the fiber can be in the form of a conjugate fiber; the can be in the form of a conjugate fiber which has a sheath core or tipped multilobal (e.g., trilobal) cross section; the fiber can be in the form of a conjugate fiber, which has a sheath core or tipped multilobal (e.g., trilobal) cross section, wherein the sheath or the tip component is a polyolefin; the core can comprise an styrene-isoprene triblock or higher copolymer; the core can comprise an styrene-isoprene pentablock or higher copolymer; or any combination thereof.

SUMM In another broad respect, this invention is an article of manufacture comprising a multifilament yarn, woven fabric or nonwoven web comprising at least one fiber made from a composition comprising 50% to 100% by weight of one or more block copolymers, wherein each block copolymer has at least two blocks produced from a vinyl aromatic monomer having up to 20 carbons and from a conjugated alkene monomer of formula: R.sub.2C.dbd.CR--CR.dbd.CR.sub.2 wherein each R, independently in each occurrence, is hydrogen or alkyl of one to four carbons or any two R form a ring, wherein the conjugated alkene monomer has at least five carbons and no more than 20 carbons. In this respect, the composition may comprise up to 50% of a processing

additive; the processing additive can be a fluorocarbon, a polyolefin, a mineral oil, a polysiloxane fluid, a tackifier, a wax, or combination thereof; the composition can include up to 5% of an additive to mitigate degradation of the fiber's properties; an additive to add color, luster, deluster, or filling; anti-block additive; a slip agent; or combination thereof; the block copolymer can be a triblock having two vinyl aromatic monomer unit blocks and one conjugated alkene monomer unit block; the block copolymer can be a pentablock having three vinyl aromatic monomer unit blocks and two conjugated alkene monomer unit blocks; the conjugated alkene monomer can be isoprene; at least one of the vinyl aromatic monomers can be styrene; the fibers can have a diameter less than 400 microns; the fiber can be in the form of a conjugate fiber; the fiber can be in form of a conjugate fiber which has a sheath core or tipped multilobal (e.g., trilobal) cross section; the fiber can be in the form of a conjugate fiber, which has a sheath core or tipped multilobal (e.g., trilobal) cross section, wherein the sheath or the tip component is a polyolefin; the core can comprise an SI triblock or pentablock or higher copolymer.

SUMM wherein the block copolymer has at least two blocks produced from a vinyl aromatic monomer and at least one block formed from a conjugated alkene monomer, and wherein the composition has an order/disorder transition (ODT) onset temperature of less than 280° C. and has a shear modulus, G', and loss modulus, G", neither of which monotonically increase with temperature in the range from the ODT, or 150° C. in the absence of an ODT, to 280° C. In this process, the composition can comprise up to 50% of a processing additive; the processing additive can be a fluorocarbon, a polyolefin, a mineral oil, a polysiloxane fluid, a tackifier, a wax, or combination thereof; the composition can include up to 5% of an additive to mitigate degradation of the fiber's properties, an additive to add color, luster, deluster, or filling, anti-block additive, a slip agent, or combination thereof; the block copolymer can be a triblock having two vinyl aromatic monomer unit blocks and one alkyl-substituted, conjugated alkene monomer unit block; the block copolymer can be a pentablock having three vinyl aromatic monomer unit blocks and two alkyl-substituted, conjugated alkene monomer unit blocks; the conjugated alkene monomer can be isoprene; the conjugated alkene monomer can be of formula R.sub.2C.dbd.CR--CR.dbd.CR.sub.2, wherein the monomer has at least five carbons, and wherein each R, independently in each occurrence, is hydrogen or alkyl of from one to four carbons or any two R may form a ring; at least one of the vinyl aromatic monomers can be styrene; the fibers can have a diameter less than 400 microns; the fibers can be in the form of a conjugate fiber; the fibers can be in the form of a conjugate fiber which has a sheath core or tipped multilobal (e.g., trilobal) cross section; the fibers can be in the form of a conjugate fiber, which has a sheath core or tipped multilobal (e.g., trilobal) cross section, wherein the sheath or the tip component is a polyolefin; the fibers comprise a core where the core comprises an styrene-isoprene-styrene triblock copolymer or a pentablock copolymer; the fiber can be a conjugate fiber, said conjugate fiber comprising the block copolymer and at least one polyolefin component, wherein said polyolefin component at least partially envelops the block copolymer; the fibers can be thermal point bonded at a temperature substantially below the normal bonding temperature of the polyolefin component, the polyolefin can comprise polyethylene, polypropylene, or combination thereof; the extruding can be at a temperature at least 10° C. above the ODT; the extruding can be

at a temperature at least 50° C. above the ODT; the heated fiber can be drawn at a velocity of 300 m/min or greater; the block copolymer can be a styrene-isoprene block copolymer having a number average molecular weight styrene content per block of the block copolymer in the range from about 6,000 to about 45,000 grams/mole and/or having a number average molecular weight isoprene content per block of the block copolymer in the range from about 20,000 to about 150,000 grams/mole, with the total weight of styrene used to make the block copolymer being 50% or less by weight.

SUMM wherein at least one block copolymer has at least two blocks produced from a vinyl aromatic monomer having up to 20 carbons and from a conjugated alkene monomer of formula: R.sub.2C.dbd.CR--CR.dbd.CR.sub.2 wherein each R, independently in each occurrence, is hydrogen, or alkyl of one to four carbons, or any two R join to form a ring, wherein the conjugated alkene monomer has at least five carbons and no more than 20 carbons. In this process, the composition can comprise up to 50% of a processing additive; the processing additive can be a fluorocarbon, a polyolefin, a mineral oil, a polysiloxane fluid, a tackifier, a wax, or combination thereof; the composition can include up to 5% of an additive to mitigate degradation of the fiber's properties, an additive to add color, luster, deluster, or filling, anti-block additive, a slip agent, or combination thereof; the block copolymer can be a triblock having two vinyl aromatic monomer unit blocks and one alkyl-substituted, conjugated alkene monomer unit block; the block copolymer can be a pentablock having three vinyl aromatic monomer unit blocks and two alkyl-substituted, conjugated alkene monomer unit blocks; the conjugated alkene monomer can be isoprene; at least one of the vinyl aromatic monomers can be styrene; the fibers can have a diameter less than 400 microns; the fibers can be in the form of a conjugate fiber; the fibers can be in the form of a conjugate fiber which has a sheath core or tipped multilobal (e.g., trilobal) cross section; the fibers can be in the form of a conjugate fiber, which has a sheath core or tipped multilobal (e.g., trilobal) cross section, wherein the sheath or the tip component is a polyolefin; the fibers can comprise a core where the core comprises an styrene-isoprene-styrene triblock or pentablock copolymer; the fiber can be a conjugate fiber, said conjugate fiber comprising the block copolymer and at least one polyolefin component, wherein said polyolefin component at least partially envelops the block copolymer; the fibers can be thermal point bonded at a temperature substantially below the normal bonding temperature of the polyolefin component; polyolefin may comprise polyethylene, polypropylene, or combination thereof; the extruding can be at a temperature at least 10° C. above the ODT; the fiber can be extruded at a temperature at least 50° C. above the ODT; the-heated fiber is drawn at a velocity of 300 m/min or greater; the block copolymer is a styrene-isoprene block copolymer having a number average molecular weight styrene content per block of the block copolymer in the range from about 6,000 to about 45,000 grams/mole and/or having a number average molecular weight isoprene content per block of the block copolymer in the range from about 20,000 to about 150,000 grams/mole, with the total weight of styrene used to make the block copolymer being 50% or less by weight; or any combination thereof.

DETD The vinyl aromatic monomer is typically a monomer of the formula: Ar--C(R.sup.1).dbd.C(R.sup.1).sub.2 wherein R.sup.1 is independently in

each occurrence hydrogen or alkyl or forms a ring with another R.sup.1, Ar is phenyl, halophenyl, alkylphenyl, alkylhalophenyl, naphthyl, pyridinyl, or anthracenyl, wherein any alkyl group contains 1 to 6 carbon atoms which may optionally be mono or multi-substituted with functional groups such as halo, nitro, amino, hydroxy, cyano, carbonyl and carboxyl. Typically the vinyl aromatic monomer has a carbon count less than 20 and a single vinyl group. In one embodiment, Ar is phenyl or alkyl phenyl, and typically is phenyl. Typical vinyl aromatic monomers include styrene (including conditions whereby syndiotactic polystyrene blocks are produced), alpha-methylstyrene, all isomers of vinyl toluene, especially para-vinyl toluene, all isomers of ethyl styrene, propyl styrene, butyl styrene, vinyl biphenyl, vinyl naphthalene, vinyl anthracene and mixtures thereof. The block copolymer can contain more than one specific polymerized vinyl aromatic monomer. In other words, the block copolymer can contain a pure polystyrene block and a pure poly-alpha-methylstyrene block or any block may be made up of mixed monomers.

DETD The conjugated alkene monomer can be any monomer having 2 or more conjugated double bonds and preferably possesses at least one alkyl substitution. Such monomers include for example 2-methyl-1,3-butadiene (isoprene), 2-methyl-1,3 pentadiene, and similar compounds, and mixtures thereof. The block copolymer can contain more than one specific polymerized conjugated alkene monomer. In other words, the block copolymer can contain a polymethylpentadiene block and a polyisoprene block or mixed block(s). In general, block copolymers contain long stretches of two or more monomeric units linked together. Suitable block copolymers typically have a weight ratio of conjugated alkene monomer unit block to vinyl aromatic monomer unit block of from about 50:50 to about 95:5, in one embodiment from about 55:45 to about 90:10, based on the total weight of the conjugated alkene monomer unit and vinyl aromatic monomer unit blocks.

DETD The block copolymer can also be branched, wherein polymer chains are attached at any point along the polymer backbone. In addition, blends of any of the aforementioned block copolymers can also be used as well as blends of the block copolymers with a minor component of either hydrogenated block copolymers or certain butadiene based SBCs or both (as long as the selection criteria given above are met for these blends). In other words, a hydrogenated SBS block copolymer or SBS block polymer can be blended with an SIS block copolymer at a level of less than 50%, preferably less than 30%, based on the total weight of all block copolymers. It should be noted here that in some productions of triblock copolymers, small amounts of residual diblock copolymers may be produced.

DETD All molecular weights, herein, are expressed in grams per mole, or Daltons. M.sub.w, as used throughout this specification, can be determined using gel permeation chromatography (GPC), which was the technique used in determining molecular weights in the examples. The molecular weight of the non-hydrogenated block polymer and properties obtained are dependent upon the molecular weight of each of the monomer unit blocks. For non-hydrogenated block polymers, molecular weights are determined by comparison to narrow polydispersity homopolymer standards corresponding to the different monomer units segments (for example, polystyrene and polyisoprene standards are used for SIS block copolymers) with adjustments based on the composition of the block copolymer. Also for example, for a triblock copolymer composed of styrene (S) and

isoprene (I), the copolymer molecular weight can be obtained by the following equation: ln(M.sub.c)=x ln(M.sub.a)+(1-x) ln(M.sub.b), where M.sub.c is the molecular weight of the copolymer, x is the weight fraction of S in the copolymer, M.sub.a is the apparent molecular weight based on the calibration for Styrene homopolymer and M.sub.b is the apparent molecular weight based on the calibration for homopolymer `b` (eg. polyisoprene). This method is described in detail by L. H. Tung, Journal of Applied Polymer Science, 24, 953 (1979). For simplicity, a single homopolymer standard (PS) was used here to reference the M.sub.w of the SBCs.

DETD The block polymer composition (that is the ratio of conjugated diene monomer unit blocks to vinyl aromatic monomer unit blocks) can be determined using proton NMR and a comparative integration technique such as that described by Santee, Chang and Morton in Journal of Polymer Science: Polymer Letter Edition, 11, 449 (1973). By way of example, a Varian Inova NMR unit set at 300 MHz for .sup.1H may be used and samples of the block polymer may be analyzed as 4% solutions (w/v) in CDCl.sub.3 (deuterochloroform).

DETD The tables below (Tables 1a, b) present the M.sub.w, % styrene, ODTs and capillary rheometry data for fiber tows prepared from various commercial SBCs. Also presented in the table are classifications of each SBC. The tables show that materials with ODTs below 280° C. may be processed at a variety of temperatures to yield fibers drawn at high velocities. Most of the materials presented in these examples are pure SBCs (some also contain residual diblock). It is anticipated that process aids will allow for lower temperature processing, faster fiber velocities, or different fiber performance, as can be seen in Example 5. The comparative example shows that butadiene-based soft blocks are difficult to spin at commercial rates. In Comparative Example 1 (see also FIG. 1B) a monotonic increase in the modulus is seen at 240° C., indicative of cross-linking in this SBC polymer. Many different classes of compounds have been investigated, as well as widely varied molecular weights (.about.60 to 150 kg/mole) and % styrene (11 to 45%). In fact both methods of producing SBCs (Sequential and Coupled) are represented in the table. In all Exemplary cases, where the fibers are drawn (not strands, which are typically 100-300 microns), the diameters of the fibers making up the tows were less than 100 microns. It is anticipated that spinning on commercial extrusion equipment and fiber spinning lines will be possible at no less than the rates presented in Table 1b, and probably faster.
